# COMMUNICABLE DISEASES

Oklahoma State Health Department Oklahoma City, Oklahoma

G. F. MATHEWS, M. D., Commissioner

In the State's program for the prevention and control of communicable diseases, the Division of Communicable Disease Control attempts to aid in the administration of the State's public health laws, rules and regulations; warms of existing or impending outbreaks of disease; assists local health officers and superintendents in locating sources of infection and establishing control measures; investigates unusual diseases; and stimulates immunization campaigns.

The effectiveness of this program depends directly upon prompt and complete reporting of morbidity. It is only through these reports from physicians, hospitals, and institutions that public health authorities can learn where, how, and among whom infectious diseases are occurring.

The State Department of Health is making every effort to secure complete and accurate information concerning communicable disease cases occurring in Oklahoma. The cooperation and interest of all those responsible for the reporting of diseases is appreciated.

G. F. Mathews, M.D., Commissioner of Health

# PUBLIC HEALTH STATISTICS OF OKLAHOMA

## COMMUNICABLE DISEASES

1946

This is the third annual edition of Part I, Communicable Diseases, of Public Health Statistics for the State of Oklahoma. It contains statistical data pertaining to cases of communicable diseases reported during the year 1946. The information has been compiled from weekly reports received from practising physicians, hospitals, clinics, and health departments. Although weekly and monthly tabulations are prepared routinely for the recognition of communicable disease problems at the time they are occurring, analyses of the annual statistics are essential for research work and for program planning in prevention and control of disease.

In order to accurately determine when, where, and among whom the diseases most frequently occur, statistics are compiled according to months in which cases occurred, counties and cities where cases originated, and according to age, sex, and race of the individuals infected. Unless the data reported are complete and accurate, the resultant statistics could give a distorted picture. Many incomplete reports are queried for data considered pertinent to the analysis of the statistics. The degree of under-reporting, of course, varies for the different diseases and can not be accurately determined. The accumulated figures for reported cases over a period of years can be safely used, however, to indicate the trend of disease incidence. Judgment must be used in studying the figures, however; some increases in disease may be due to better diagnostic procedures and more complete reporting rather than to actual increases in incidence. Comparing the number of reported cases with the number of deaths from the specific communicable diseases also indicates the extent of the problem. For this report, provisional figures for resident deaths have been used for comparison and for computing case fatality rates. Final mortality figures will be published in Fart II of Fublic Health Statistics.

Insofar as possible the procedures used in preparing the data were directed toward determining the source of problems in relation to the needed control procedures. Cases have been allocated to the place where the disease was contracted, usually the county of residence. Diseases reported by military installations have been included in State totals, since they would be a potential source of infection for the resident population, but have not been allocated to individual counties because the military officials would be responsible for the control of diseases within the installations instead of local health authorities. Duplicate reports have been eliminated to avoid any possible exaggeration of a problem; tuberculosis and venereal disease cases were checked by accumulative case registries to clear out previously reported cases. Death certificates have been used as a source of determining the extent of under-reporting; deaths not otherwise reported as cases were included in

the annual tabulations. These cases reported by death certificates only for selected communicable diseases are shown in Table 1. Early reporting of communicable diseases is essential for effectively preventing spread of infections.

#### Table 1

	Septio sore throat  Septio sore throat  18  Tuberculosis, all forms  2,66  Typhoid and paratyphoid fevers  5	Dysentery 80 Encephalitis, infectious 24 Influenza 6,585 Meningitis, meningococcus 77 Pheumonia, all forms 1,709 Poliomyelitis, acute 434 Rocky Mountain spotted fever 30	Number Reported  Disease Cases  Diphtheria 222
	5 18 337	26 4 3 4 3 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4	Repo by I Certii
16.7	0.9 10.0 12.7	23.8 0.5.5 1.4.3 10.0	Per Cent Reported by Death Certificates

For comparison of disease experiences in one year with another or in the State with other states, rates are computed, based on the number of reported cases and the estimated resident populations. During the years 1940-1946, the population shifts brought on by war activities and the readjustment period made the computation of logical estimates exceedingly difficult. The population estimates for the years 1940-1944 were based on the 1940 Census enumeration and ration book No. IV count. The latter excluded military personnel and was believed to be somewhat less than the actual population due to under-registration. The 1945 and 1946 estimates include military personnel, since many were returning to civilian status. Population trends between the 1930 and 1940 census enumerations in comparison with ration book registration were used in computing the estimates for those two years.

#### Diphtheri

The morbidity rate for diphtheria continued downward, resching a new low in 1946. Only 222 cases were reported, giving a rate of 9.3 per 100,000 estimated population as compared with 12.6 in the preceding year. Although the death rate from this disease had increased during the years 1944 and 1945, provisional figures for 1946 indicate that the death rate dropped back to a low level of 1.1 per 100,000 estimated population. As shown by the data in Table 2, the case fatality rate for 1946 was 11.7, which also showed a corresponding drop from 17.0 in 1945.

Reported Cases and Deaths from Diphtheria by Age Groups

Age Group Re	Reported Cases	Deaths	Case Fatality
Total	222	26	11.7
Under 1 year 1-4 years 5-9 years 10 years and over Unknown	7.88.5 7.74 7.74 7.74 7.74 7.74 7.74 7.74 7.	1 6 4 1	15.7 18.4 1.4

Approximately 65 per cent of the cases were in children under ten years of age and 16 per cent were ten to fifteen years of age. The case fatality rate was highest in the 5-9 age group, with 18.4 per cent of the cases in that group dying. Of the total cases under ten years of age 16.1 per cent died.

#### Malaria

The 1946 figures for reported cases of malaria showed a tremendous reduction, 72.0 per cent from the 1945 figure. The majority of the 308 cases that were reported apparently contracted the disease in Southeast Oklahoma, with 56 cases in Chootaw County, 48 in McCurtain County, 53 in McIntosh County, and 44 in Okmulgee County, Atoka County, which had shown a high incidence of malaria in the previous five-year period, reported no cases in 1946. Chootaw County had not shown an unusual number of cases for the preceding five years; however, the 56 cases in 1946 was a 60 per cent increase over the five-year average. The decrease of malaria cases in 1946 from the previous five-year period is shown in Table 3 for each of those counties which had reported a high incidence.

Table 2

Decrease in Reported Cases of Malaria for Counties Having a High Incidence

Ate 7,474 1,495 308  1,333 267 - 252 50 10 1,120 224 48 2,668 534 53 321 64 44	County	Number Cases 1941-1945	Five-Year Average	Number Cases 1946	Per Cent
1,333 267 - 10 252 50 10 1,120 224 48 2,668 534 53 321 64 44	Entire State	7,474	1,495	308	79.4
	Atoka Johnston McGurtain McIntosh Okmulgee	1,333 252 1,120 2,668 2,668	64 64 64	48 48 44 44	100.0 80.0 78.6 90.1 31.3

Only nine of the cases, which apparently acquired the infection in Oklahoma, were in the military population. In addition to the cases of malaria contracted in the State, reports were received for 187 cases among veterans who had contracted the disease outside the United States.

Table 4 lists the counties with the highest death rates from malaria during the last five-year period, 1942-1946. The rates, which are based on the number of deaths per 100,000 estimated population in each county, also indicate the location and extent of the malaria problem in Oklahoma. Nearly all of the counties are in the Southeast section of the State.

Table

Counties Having Highest Malaria Death Rates, 1942-1946

Pushmataha Jefferson	Choctaw	McCurtain	Entire State	County
5.0 4.7	5.7	7.4	0.9	Rate
Sequoyah Muskogee	Fictsourg	Bryan	Atoka	County
N N N &	ب س ب ب	. w c	7 u	Rate

#### Measle

The State experienced an epidemic of measles during the Spring of 1946, with 3,338 cases reported during the months March, April, and May. This was 76.1 per cent of the total 4,387 reported cases for the year.Of those cases with ages specified, 1,904 or 79.7 per cent were under ten years of age. The death rate of 1.3 and the case fatality rate of 0.7 were both higher than for the preceding year, when the rates were 0.2 and 0.5, respectively. Table 5 shows the measles cases and deaths by age groups. In addition there were 225 cases of German measles reported during the year.

Reported Cases and Deaths from Measles by Age Group

Age Group	Reported Cases	Deaths	Case Fatality Rate
Total	4,387	22	0.7
Under 1 year 1-4 years 5-9 years 10 years and over Unknown	58 758 1,088 485 1,998	1335	2.1 2.1 2.1

Since many additional cases of messles were not attended by physicians and were unreported, queries were sent to local health authorities in each county requesting that the schools be contacted and estimates made of the number of children absent because of messles during the months March and April. Replies indicated that there were over 16,000 unreported cases of messles among the school children, 12,000 in March and 4,000 in April. Although these cases could not be included in tabulations of reported cases, the figures do intimate that there were approximately 20,000 cases of messles during the year, mostly among school children.

## Meningococcus Meningitis

Although the 77 reported cases of meningococcus meningitis in Oklahoms in 1946 were a reduction from the 84 cases in the previous year, the incidence of this disease was still higher than for the years 1938-1942. The attack rate was only 8.6 per cent less than in 1945, but the case fatality rate of 18.2 was 38.9 per cent less than the rate of 29.8 in 1945.

Table 6

Reported Cases and Deaths from Meningococcus Meningitis
by Age Groups

7.00 8 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	18.2	Case Fatality Rate

#### Poliomyelitis

The year 1946 was another peak year for pollomyelitis, with 434 cases reported, giving a rate of 18.2 per 100,000 estimated population. This epidemic still did not approach the 594 cases which occurred in 1943 when the rate was 28.7. The rate for the white population was 19.4 cases, four and a half times as high as the rate for the non-whites. Of the total cases reported, 370 or 85.6 per cent were under 15 years of age. The 34 deaths brought the case fatality rate up to 7.8 over the 6.5 in 1945. The fatality rate was highest in those children 5-14 years of age. Table 7 shows the distribution of the cases and deaths by age groups.

Reported Cases and Deaths from Poliomyelitis
by Age Groups

Age Group	Reported Cases	Desths	Case Fatality
Total	434	34	7.8
Under 1 year 1-4 years 5-9 years 10-14 years 15 years and over Unknown	13 141 129 87 62 2	10 10 6	9.75 11.66

At least 65 per cent of the cases occurred during the hot months multy, August, and September. Some delayed reports received in later months may have included other cases whose onset was in those months also. Ottawa County reported the highest incidence rate, with 30 cases and a rate of 33,7 cases per 100,000 estimated population. Only two deaths were reported for Ottawa County. Oklahoma and Tulsa Counties reported the largest number of cases, 67 and 61, respectively, but the rates for these counties, 23.8 and 26.5, were low in comparison with some of the counties with smaller populations. Grant, Noble, and Woods Counties had rates around 40, and eight counties had rates between 30 and 40. Six of the deaths were recorded for Oklahoma County and 4 for Tulsa County.

## Respiratory Streptococcal Infection

rewer cases of respiratory streptococcal infections, scarlet fever and septic sore throat, were reported than for any year for which records are available. Only 546 cases of scarlet fever and 180 cases of septic sore throat were reported; the combined total was 39.3 per cent less than for the previous year. The military population had only 55 cases of scarlet fever and one septic sore throat reported. More cases seemed to have occurred during the months January-April, with 55 per cent of the civilian cases reported during those four months. The distribution by age group of the cases for both diseases is shown in Table 8.

Reported Cases and Deaths from Respiratory Streptococcal Infections by Age Groups

	Sce	Scarlet Fever	Tev	Septic	Septic Sore Throat	hroat
Age Group	Reported Cases	Deaths	Fatality Rate	Reported Cases	Deaths	Fatality Rate
Total	546	6	1.	180	19	10.6
Under 1 year 1-4 years 5-9 years 10 years and over Unknown	118 202 165 47	10001	1.7	12 15 15 15	. g + ~ ~	100.0 15.6 6.7 8.5

The fatality rate of 10.6 for septic sore throat was considerably higher than the rate of 1.1 for scarlet fever; this difference may be

due partly to greater under-reporting of septic sore throat. The case fatality rate for the children under five years of age having septic sore throat was around 22.9.

## Pneumonia and Influenza

During the year,1,709 cases of pneumonia and 6,585 cases of influence were reported, with 88.6 per cent of the cases occurring in January, February, March, and November and December. The combined fatality rate for the two diseases was 11.5, which was probably too high since it is believed that the actual number of cases of the two diseases far exceeded the number diagnosed and reported by physicians. The very high percentage of these cases reported by death certificates indicated that the diseases were poorly reported.

The rates for these respiratory diseases were extremely high among the Indians, with a rate of 333.9 cases for influenza and 184.7 for pneumonia. The Negro rate of 69.2 for influenza was lower than the white rate, 107.8; the rates for pneumonia, on the other hand, were 92.0 for the Negroes and 65.0 for the whites.

### Whooping Cough

Reports of whooping cough cases during 1946 totaled 479, with a rate of 20.1 per 100,000 estimated population. The Indian rate of 51.5 was high in comparison to 15.6 for the white population and 6.3 for the Negroes. About 20 per cent of the reported cases with ages specified were under one year of age. The cases fatality for this group was also high, with 21.1 per cent of the cases dying; all of the deaths were of children under five years of age, with a fatality rate of 10.6. Table 9 shows the age distribution of the cases and deaths.

Table S

Reported Cases and Deaths from Whooping Cough by Age Group

Age Group	Reported Cases	Deaths	Case Fatality
Total	479	25	5.2
Under 1 year 1-4 years 5-9 years 10 years and over Unknown	76 160 119 21 103	1 1 9 16	21.1 5.6

## Other Acute Communicable Diseases

A new low record. was made with only 58 cases of <u>typhoid</u> and <u>paratyphoid fevers</u> reported. This was 42 per cent lower than for the previous year. Seven deaths from the diseases occurred during the year, giving a fatality rate of 12.1.

Dysentery also showed a decrease in incidence, from 211 cases in 1945 to 80 in 1946. The case rate was reduced 61.8 per cent. There were 46 cases of amoebic dysentery, 16 of bacillary, and 18 unspecified.

During the months April through September, 30 cases of <u>Rocky Mountain spotted fever</u> were reported. Six of the cases were Indian, giving a rate of 10.7 cases in comparison to the rate of 1.0 for the whites. Most of the cases were in the younger age group; 67 per cent were under 20 years of age. Five deaths were recorded from this disease, making a fatality rate of 16.7.

A total of 16 cases of <u>smallpox</u> were reported, which was a slight increase over the figures for the two years immediately preceding. Bryan and Stephens Counties reported four cases each, but the remaining cases were somewhat scattered, only one in a county. No deaths were recorded.

More cases of tularemia, 86, were reported than for any previous year for which records are available. The rate of 3.6 was two and a half times higher than the average rate for the previous five years. This increase in the number of reported cases was probably due largely to the inclusion of cases who had positive laboratory tests made at the State Laboratory and were not otherwise reported. The case fatality rate was low, however, since only two deaths were recorded.

The six typhus fever cases reported also represented a larger number than recorded before. The previous ten years averaged only two cases per year.

Undulant fever cases totaled 36, giving a rate of 1.5, which was in line with the lowest rates in 1943 and 1945. No serious outbreaks were reported, but McCurtain County reported 6 cases, Garfield 5, and Tulsa City 5. The other cases were distributed with only one, two, or three in a county.

Six cases of <u>erysipelag</u> were recorded during the year. These cases, which were not included in the tables, occurred in Adair, Grady, Kay, Marshall, Osage, and Tulsa Counties. <u>Puerperal septicemia</u>, another streptocal infection, was reported on four death certificates.

Two fatal cases of <u>rabies</u> occurred during the year, one in Comanche County and one in Tulsa. One case of <u>glandular fever</u>, which has not been included in the tabulations, was reported from McCurtain County.

þ

#### luberculosis

The number of newly reported cases of tuberculosis was still on the increase during 1946; 2,664 cases were reported, which was 18.6 per cent more cases than were counted in 1945. Of the total number, 2,602 were respiratory and 62 were other forms of tuberculosis. Six of the cases were military personnel. The increasingly large number of reported cases each year has been brought about by the extension of diagnostic and case-finding programs and the cooperation of sanatoria and local health departments in the interchange of information with the State Department of Health. Fire counties conducted mass x-ray surveys during 1946. Table 10 shows the reported cases according to stage and activity or type of disease, by race.

Table 10
Reported Cases of Tuberculosis by Type,
Stage and Activity, and by Race

Meninges Intestines and peritoneum Vertebral column Bones and joints Skin Lymphatic system Genito-urinary system Other organs Miliary	Tuberculosis of:	Minimal, active Mod. Adv., active Far Adv., active Arrested (any stage) Ap. cured (any stage) Unqualified	Tuberculosis of Respiratory System:
13 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1	62	264 307 328 624 34 1,045	<u>Total</u> 2,602
000411115	34	175 206 209 524 32 804	White 1,950
<i>א</i> שרשוורו א	17	17 32 34 37 117	<u>Negro</u> 237
אוווטווט	9	81 284 43 45	Indian 253
	ν	2842 8848 8848 8848	<u>Unkno</u> mn 162

There were 111.8 new cases reported per 100,000 estimated population, which is the second highest rate on record; in 1944 the rate was 141.2. The Indian rate was very high with 465.4 cases reported per 100,000 estimated Indian population. The Negro rate was also high in comparison to the white, with 145.2 for the Negroes and 92.2 for the whites.

About 66 per cent of the cases reported were between the ages 20-54. A surprisingly large number were in the older age group; in fact, 62 per cent of the cases were over 35 years of age. Since 42.3 per cent of the cases reported for the first time, with stage and activity specified, were either arrested, or apparently cured and another 21.1 per cent were that dranced, it appears that many cases were not early diagnoses or that the initial reports were delayed. This may account partly for a large percentage of cases in the older age groups who were reported for the first time.

Although the reporting of tuberculosis has definitely improved, earcases are needed for further study of the problem in Oklahoma. The status of 40 per cent of the cases reported during the year was unknown at the time of report. The high percentage of cases reported by sanstoris, dication that many cases were not reported when first discovered, Early measures. Table 11 shows the number and per cent of civilian cases reported according to the source of the first report education cases reported when first discovered, Early follow-up of cases and contacts is essential for treatment and control measures. Table 11 shows the number and per cent of civilian cases reported according to the source of the first report received.

Table 11

20.0 20.0 10.0 5.5 18.9 1.8	100.0	Per Cent	

## Venereal Diseases

Cases of gonorrhea showed a 20 per cent increase over the previous year. The rate for the Negroes was the highest, with 2,296.8 cases per 100,000 Negro population. The Indian rate was 532.9, and the white, 295.0 cases. About 59 per cent of the cases were male.

An increase of 32.2 per cent in the number of syphilis cases was recorded. The Negro rate of 1,684,6 was eight times as high as the white rate, 200.0. Only 23 per cent of the cases were primary and secondary, while 40 per cent were late and late latent. Almost six per cent, 383 cases, were congenital syphilis. Table 12 shows the reported cases of venereal diseases by stage of disease and sex.
